Logistic Regression

Step 1: Function Set

We want to find $P_{w,b}(C_1|x)$

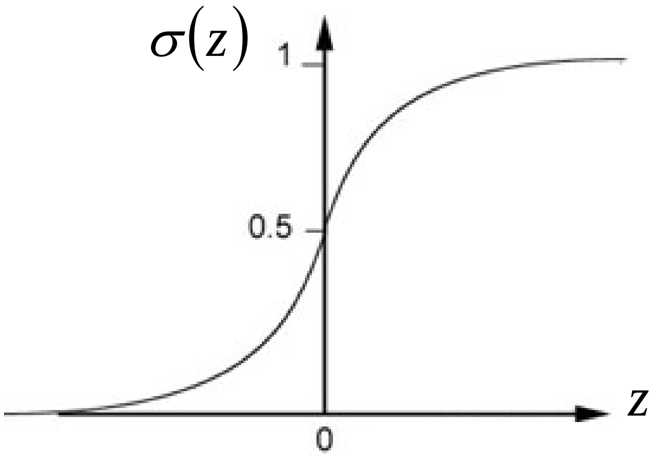
If $P_{w,b}(C_1|x) \geq 0.5$, output C_1

Otherwise, output C_2

$$\boxed{P_{w,b}(C_1|x) = \sigma(z)}$$

$$z = w \cdot x + b$$

$$\boxed{\sigma(z) = \frac{1}{1 + exp(-z)}}$$



Function set:

$$f_{w,b}(x) = P_{w,b}(C_1|x)$$

Including all different w and b

Step 1: Function Set

Assume the data is generated based on $f_{w,b}(x) = P_{w,b}(C_1|x)$

Given a set of w and b, what is its probability of generating the data?

$$\boxed{L(w,b) = f_{w,b}(x^1)f_{w,b}(x^2)\left(1 - f_{w,b}(x^3)\right)\cdots f_{w,b}(x^N)}$$

Logistic Regression | Linear Regression

Logistic Regression

Step 1: $f_{w,b}(x) = \sigma\left(\sum_i w_i x_i + b\right)$

Output: between 0 and 1

Step 2: Training data: $(x^n, \hat{y}^n)$

$\hat{y}^n$: 1 for class 1, 0 for class 2

$$L(f) = \sum_n \boxed{C(f(x^n), \hat{y}^n)}$$

Linear Regression

Step 1: $f_{w,b}(x) = \sum_i w_i x_i + b$

Output: any value

Step 2: Training data: $(x^n, \hat{y}^n)$

$\hat{y}^n$: a real number MSE

$$L(f) = \boxed{\frac{1}{2}\sum_n (f(x^n) - \hat{y}^n)^2}$$

$$C(f(x^n), \hat{y}^n) = -\left[\hat{y}^n \ln f(x^n) + (1 - \hat{y}^n)\ln\left(1 - f(x^n)\right)\right]$$

Question: Why don't we simply use square error as linear regression?

Step 3: Find the best function

$$\frac{-\ln L(w,b)}{\partial w_i} = \sum_n -\left[\hat{y}^n \boxed{\frac{\ln f_{w,b}(x^n)}{\partial w_i}} + (1-\hat{y}^n)\frac{\ln\left(1-f_{w,b}(x^n)\right)}{\partial w_i}\right]$$

$$f_{w,b}(x) = \sigma(z)$$

$$= 1/(1+exp(-z))$$

$$z = w \cdot x + b = \boxed{\sum_i w_i x_i + b}$$

Step 3: Find the best function

- Benefit of generative model
  - With the assumption of probability distribution, less training data is needed
  - With the assumption of probability distribution, more robust to the noise
  - Priors and class-dependent probabilities can be estimated from different sources.
